YUV and luminance considered harmful

This is a plea for precise terminology in video. The notation YUV, and the term luminance, are widespread in digital video. In truth, digital video almost never uses Y'UV color difference components, and never directly represents the luminance of color science. The common terms are almost always wrong. This note explains why. I urge video engineers and computer graphics specialists to use the correct terms, almost always Y’C’B’C’R and luma.

Cement vs. concrete

I’ll demonstrate by analogy why it is important to use correct terms. Next time you’re waiting in line for a bus, ask the person next to you in line what building material is used to construct a sidewalk. Chances are that person will answer, “cement.”

The correct answer is concrete. Cement is calcined lime and clay, in the form of a fine, gray powder. Cement is one ingredient of concrete; the other ingredients are sand, gravel, and water.

In an everyday situation, you need not be precise about which of these terms are used: If you refer to a bridge as being constructed of “cement,” people will know what you mean. Lay people are not confused by the term “cement.” Interestingly, experts are not confused either. If a bridge superintendent yells out to his foreman, “Get me 500 pounds of cement!” the foreman understands immediately from context whether the superintendent actually wants concrete. However, if you place an order with a building material supplier for 500 pounds of cement, you will certainly not receive 500 pounds of concrete! Lay people have no trouble with the loose nomenclature, and the experts have little trouble. It is the people in the middle who are liable to become confused by loose nomenclature. Worse still, they are liable to use a term without realizing that it is ambiguous or wrong!

True CIE luminance

The principles of color science dictate that true CIE luminance – denoted Y – is formed as a weighted sum of linear (tristimulus) RGB components. If CIE luminance were transmitted in a video system, the system would conform to the Principle of Constant Luminance. But in video we implement an engineering approximation that departs from
$601Y' = 0.299R' + 0.587G' + 0.114B'$

Poynton, Charles, Digital video and HDTV algorithms and interfaces (San Francisco: Morgan Kaufmann, 2003).

this principle. It was standardized for NTSC in 1953, and remains standard for all contemporary video systems, to form luma, denoted $Y'$, as a weighted sum of nonlinear (gamma-corrected) $R'G'B'$ components. The nonlinear transfer function is roughly comparable to a square root. To form luma, we use the theoretical coefficients of color science, but we use them in a block diagram different from that prescribed by color science: As detailed in my book, in video, gamma correction is applied before forming the weighted sum, not after. The “order of operations” is reversed from what you might expect from color science.

The misinterpretation of luminance

Video engineers in the 1950s recognized that the video quantity $Y'$ was very different from CIE luminance, and that it needed to be distinguished from luminance. They described it by the phrase the quantity representative of luminance. They used the symbol $Y$, but augmented it with a prime to denote the nonlinearity: $Y'$. Obviously the qualifier “quantity representative of” was cumbersome, and over the decades, it was elided. And over time, the prime symbol was elided as well. Unfortunately, no new word was invented to supplement luminance, to reinforce the distinction between the color science quantity and the video quantity. Most video engineers nowadays are unfamiliar with color science, and most do not understand the distinction. Engineers today often carelessly use the word luminance, and the symbol $Y$, to refer to the weighted sum of nonlinear (gamma-corrected) $R'G'B'$ components.

The sloppy nomenclature made its way into ostensibly authoritative video references, such as Pritchard’s SMPTE paper published in 1977.

The computer graphics pioneer Alvy Ray Smith encountered the word luminance in his quest to adapt video principles to computer graphics. Smith apparently correlated the use of the term luminance with his knowledge of color science, and understandably – though mistakenly – concluded that video “luminance” and color science luminance were identical. Consequently, video YIQ was introduced to computer graphics, having its $Y$ component alleged to be identical to CIE luminance.

That incorrect interpretation propagated into authoritative computer graphics textbooks. Computer Graphics: Principles and Practice, on page 589, Section 13.3.3, The YIQ Color Model, states:

The $Y$ component of YIQ is not yellow but luminance, and is defined to be the same as the CIE Y primary.

(The emphasis is in the original. “Yellow” refers to CMY, which was mentioned in the immediately preceding section. “CIE Y primary” would be more accurately denoted “CIE Y component.”)

As you have seen, the so-called $Y$ component of video – more properly designated with a prime symbol, $Y'$ – is not the same as CIE luminance. Video $Y'$ cannot even be computed from CIE $Y$, unless two other color components are also available. The quoted passage is quite wrong.
About 300,000 copies of various editions and adaptations of *CG:PP* have been printed. Confusion is rampant.

The error also propagated into the digital image processing community. A widely used book in that field states:

N.T.S.C. formulated a color coordinate system for transmission composed of three tristimulus values YIQ. The $Y$ tristimulus value is the luminance of a color.

The video quantities are certainly *not* tristimulus values, which are, by CIE’s definition, proportional to intensity.

Loose nomenclature on the part of video engineers has misled a generation of digital image processing, computer software, and computer hardware engineers.

**The enshrining of luma**

I campaigned for adoption of the term *luma* to designate the nonlinear video quantity. The term had no pre-existing meaning, and by virtue of its being different from *luminance*, it invites readers from other domains to investigate fully before drawing conclusions about its relationship with luminance.

With the help of Fred Kolb, my campaign succeeded: In 1993, SMPTE adopted Engineering Guideline EG 28, *Annotated Glossary of Essential Terms for Electronic Production*. EG 28 defines the term *luma*, and clarifies the two conflicting interpretations of the term *luminance*. While a SMPTE EG is not quite a SMPTE “Standard,” at long last the term has received official recognition. There’s no longer any excuse for sloppy use of the term *luminance* by the authors of video engineering papers.

It is a shame that today’s SMPTE and ITU-R standards for digital video persist in using the incorrect word *luminance*, without ever mentioning the ambiguity – even conflict – with the CIE standards of color science.

**Color difference scale factors**

To represent color, luma is accompanied by two *color difference* – or *chroma* – components, universally based on *blue minus luma* and *red minus luma*, where blue, red, and luma have all been subject to gamma correction: $B' - Y'$ and $R' - Y'$. Different scale factors are applied to the basic $B' - Y'$ and $R' - Y'$ components for different applications. $Y'P_B P_R$ scale factors are optimized for component analog video. $Y'C_B C_R$ scale factors are optimized for component digital video such as 4:2:2 studio video, JPEG, and MPEG. Kodak’s PhotoYCC ($Y'C_1 C_2$) uses scale factors optimized to record the gamut of film colors. $Y'U V$ and $Y'I Q$ use scale factors optimized to form composite NTSC and PAL video.

$Y'C_B C_R$ scaling as defined by Rec. 601 is appropriate for component digital video. $Y'C_B C_R$ chroma is almost always subsampled using one of three schemes: 4:2:2, or 4:2:0, or 4:1:1.
Y’U’V’ scaling is properly used only as an intermediate step in the formation of composite NTSC or PAL video signals. Y’U’V’ scaling is not appropriate when the components are kept separate. However, the Y’U’V’ nomenclature is now used rather loosely, and sometimes – particularly in computing – it denotes any scaling of B’—Y’ and R’—Y’.

Digital disk recorders (DDRs) are generally able to transfer files across Ethernet. Abekas introduced the convention of using an extension “.yuv” for these files. But the scale factors – in Abekas equipment, at least – actually correspond to Y’C’B’C’R’. Use of the “.yuv” extension reinforces the misleading YUV nomenclature.

Subsampling is properly performed only on component digital video, that is, on Y’C’B’C’R’. Subsampling is inappropriate for Y’U’V’. If you see a system described as Y’U’V’ 4:2:2, you have a dilemma. Perhaps the person who wrote the description is unfamiliar with the principles of component video, and the scale factors actually implemented in the equipment (or the software) are correct. But you must allow for the possibility that the engineers who designed or implemented the system used the wrong scale factors! If the wrong equations were used, then color accuracy will suffer; however, this can be difficult to diagnose.

Proper Y’C’B’C’R’ scaling is usual in Motion-JPEG, and in MPEG. However, the Y’C’B’C’R’ scaling used in stillframe JPEG/JFIF in computer applications usually uses “full-range” (or “full-swing”) luma and chroma excursions, without any headroom or footroom. The chroma excursion is 254⁄255 of the luma excursion. The scaling is almost exactly that of Y’P’B’P’R’, but is unfortunately described as Y’C’B’C’R’. Now even Y’C’B’C’R’ is ambiguous! I am hopeful that proper Y’C’B’C’R’ scaling will be incorporated into the next revision of JFIF, so that compressed stillframe and motion imagery in computing can be combined without suffering a conversion process.

Except for very limited use in the encoding and decoding of composite 4f’ SC (or loosely, “D-2”) studio video, Y’I’Q coding is obsolete.

**Conclusion: A plea**

Using the term luminance for video Y’ is tantamount to using the word cement instead of concrete to describe the main construction material of a bridge. Lay people don’t care, and experts can live with it, but people in the middle – in this case, the programmers and engineers who are reimplementing video technology in the computer domain – are liable to draw the wrong conclusions from careless use of terms. Users suffer from this, because the exchange of images is compromised.

I urge video engineers and computer graphics specialists to avoid YUV and luminance, and to use the correct terms, Y’C’B’C’R’ and luma.
